Identifying Age-Related Conditions

1.1. Import Libraries

In [2]:
```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
from matplotlib.ticker import FuncFormatter
%matplotlib inline
import seaborn as sns
from xgboost import XGBClassifier
from lightgbm import LGBMClassifier
from sklearn.linear_model import LogisticRegression
from sklearn.svm import SVC
import random
from scipy.stats import uniform, randint

# Suppress any warnings
import warnings
warnings.filterwarnings('ignore')

# Sklearn
from sklearn.model_selection import train_test_split, RandomizedSearchCV, StratifiedKFold, GridSearchCV
from sklearn import metrics

# kNN Imputation
from sklearn.impute import KNNImputer

# Feature Selection
from sklearn.feature_selection import SelectKBest, f_classif

# Data Encoder and Scaler
import category_encoders as encoders
from sklearn.preprocessing import LabelEncoder, RobustScaler

# SMOTE (Synthetic Minority Over-sampling Technique)
from imblearn.over_sampling import SMOTE
```

```
/opt/conda/lib/python3.10/site-packages/scipy/__init__.py:146: UserWarning: A NumPy version >=1.16.5 and <1.23.0 is req
uired for this version of SciPy (detected version 1.23.5
  warnings.warn(f"A NumPy version >={np_minversion} and <{np_maxversion}"
```

1.2. Load the Data

In [3]:
```
# Read the train, test and greeks data

df_train = pd.read_csv("/input/icr-identify-age-related-conditions/train.csv")
df_test = pd.read_csv("/input/icr-identify-age-related-conditions/test.csv")
df_greeks = pd.read_csv("/input/icr-identify-age-related-conditions/greeks.csv")

print('No. of records for train : {}'.format(df_train.shape))
print('No. of records for test : {}'.format(df_test.shape))
print('No. of records for greeks : {}'.format(df_greeks.shape))
```

```
No. of records for train : (617, 58)
No. of records for test : (5, 57)
No. of records for greeks : (617, 6)
```

2. EDA

2.1. Distribution of Target Label

To check if the distribution of target feature (i.e. Class) is balanced. If it is not the case, we will do oversampling of SMOTE (Synthetic Minority Over-sampling Technique) algorithm in the modelling process.

In [4]:
```
# check whether the data set is balanced

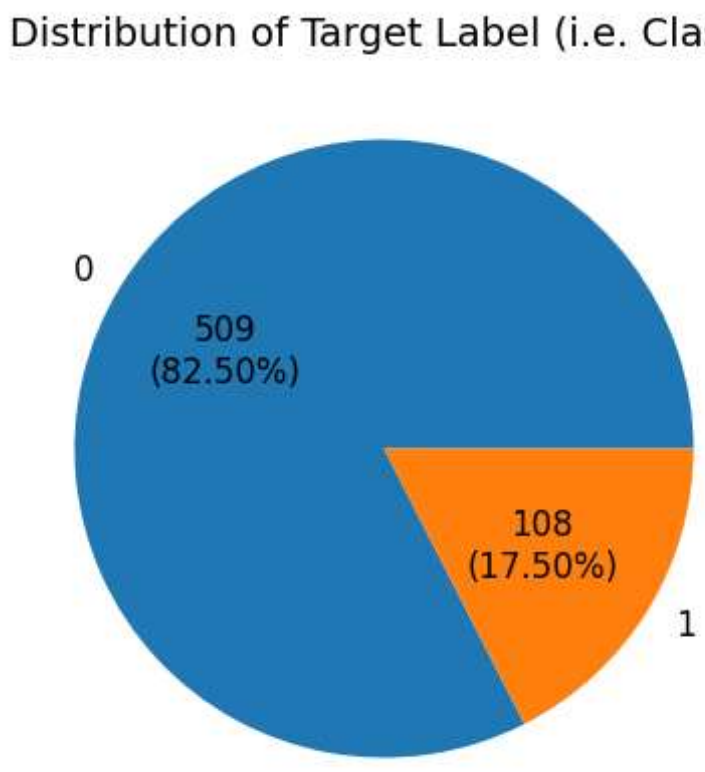
plt.figure(figsize=(5,5))

def auto_fmt (pct_value):
    return '{:.0f}\n({:.2f}%)'.format(df_train['Class'].value_counts().sum()*pct_value/100,pct_value)

df_transported_count = df_train['Class'].value_counts().rename_axis('Class').reset_index(name='Counts')

fig = plt.gcf()
plt.pie(x=df_transported_count['Counts'], labels=df_transported_count['Class'], autopct=auto_fmt, textprops={'fontsize'
plt.title('Distribution of Target Label (i.e. Class)',  fontsize = 14)
```

Out[4]:
```
Text(0.5, 1.0, 'Distribution of Target Label (i.e. Class)')
```



Observation: the distribution of target feature between 1 and 0 cases is uneven. It may be necessary to do oversampling, e.g. SMOTE (Synthetic Minority Over-sampling Technique).

2.2. Missing Value Analysis

Missing values in machine learning can have a significant impact on the performance and accuracy of models, and most machine learning algorithms cannot handle missing value. To address missing values, imputation techniques are often used to estimate or fill in the missing data.

In [5]:
```
# Only include numerical features
df_train_numerical = df_train.drop(['Id', 'EJ', 'Class'], axis=1)
```

In [6]:
```
plt.figure(figsize=(10, 6))

# No. of missing values by features
df_train_missing = df_train_numerical.isna().sum()

# Resetting the index
df_train_missing = df_train_missing.reset_index()

# Renaming the columns
df_train_missing.columns = ['feature', 'missing_count']

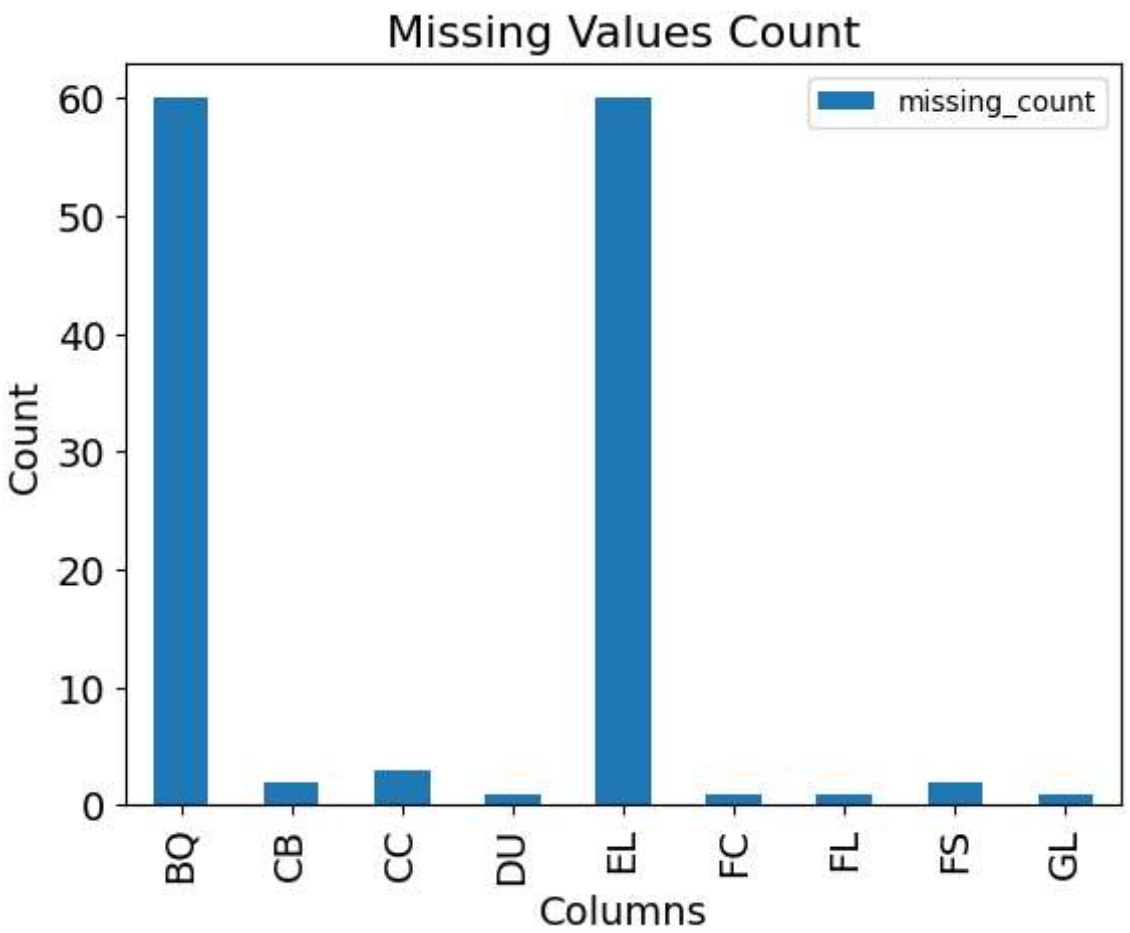
# Filtering features with missing values
df_train_missing = df_train_missing.loc[df_train_missing['missing_count'] > 0]

# Create a bar chart
df_train_missing.plot.bar(x='feature', y='missing_count')

# Set the chart title and axis labels
plt.title('Missing Values Count', fontsize=16)
plt.xlabel('Columns', fontsize=14)
plt.ylabel('Count', fontsize=14)
plt.tick_params(axis='x', which='major', labelsize=14)
plt.tick_params(axis='y', which='major', labelsize=14)

# Display the chart
plt.show()
```

```
<Figure size 1000x600 with 0 Axes>
```



Observations: The features BQ and EL exhibit a high number of missing values, while some other features also have a few missing values. In order to tackle this issue, we will perform imputation to handle the missing values.

2.3. Descritpive Analysis

Descriptive analysis refers to the process of summarizing and interpreting data to gain insights and understand its main characteristics. It involves the use of various statistical measures and visualization techniques to describe and present data in a meaningful way.

In [7]:
```
# Exclude the target label Class and categorical feature EJ in the Describe analysis
# Since there are too many colums for Describe analysis, we need to transpose the results.

df_train_numerical.describe(include='all').transpose()
```

2.4. Histogram Analysis for Skewness

It examines the shape of the distribution displayed in a histogram to determine the skewness of the data.

In [8]:
```
# Histgram for numercial features
fig, ax = plt.subplots(11, 5, figsize=(16,30))

for i in range(0, (len(ax.flatten()))):
#     print('{}, {}'.format(int(i/5),i % 5))
    sns.histplot(data=df_train_numerical, x =df_train_numerical.iloc[:,i], bins=20, ax=ax[int(i/5),i % 5])
#     ax[int(i/5), i % 5].set_title(df_train_numerical.columns[i])

# Adjust the vertical spacing between subplots
plt.subplots_adjust(hspace=0.5)

plt.show()
```

2.5. Boxplot Analysis for Outliers

It identifies and analyzes outliers in a dataset. A boxplot is a graphical representation that displays the distribution of data and provides insights into the presence of outliers. Here's how you can perform boxplot analysis for outliers

In [9]:
```
# Histgram for numercial features
fig, ax = plt.subplots(11, 5, figsize=(16,30))

for i in range(0, (len(ax.flatten()))):
    sns.boxplot(x="Class",y=df_train_numerical.columns[i],data=df_train, ax=ax[int(i/5),i % 5])

# Adjust the vertical spacing between subplots
plt.subplots_adjust(wspace=0.3)

plt.show()
```

Class

Observations: based on the descriptive and histogram analysis, it is evident that the numerical features display different variances and distributions. To ensure consistency and comparability, it is crucial to standardize the features by rescaling them before proceeding with the modeling process.

Furthermore, the box plot analysis reveals the presence of outliers in several numerical features. To address the skewness and outliers effectively, we propose utilizing the Robust Scaler for standardizing the numerical features.

The Robust Scaler is well-suited for this task as it can automatically handle outliers during the scaling process, providing robustness to extreme values. By employing the Robust Scaler, we can mitigate the impact of outliers and achieve a more reliable and accurate modeling outcome.

2.6. Count Plot for Distribution of Categorical Features

This plot is a type of visualization that displays the distribution of categorical features in a dataset. It represents the frequency or count of each category or class within a categorical variable.

In [10]:
```
# Set the size of the chart
plt.figure(figsize=(5, 4))
plt.legend(fontsize=13)

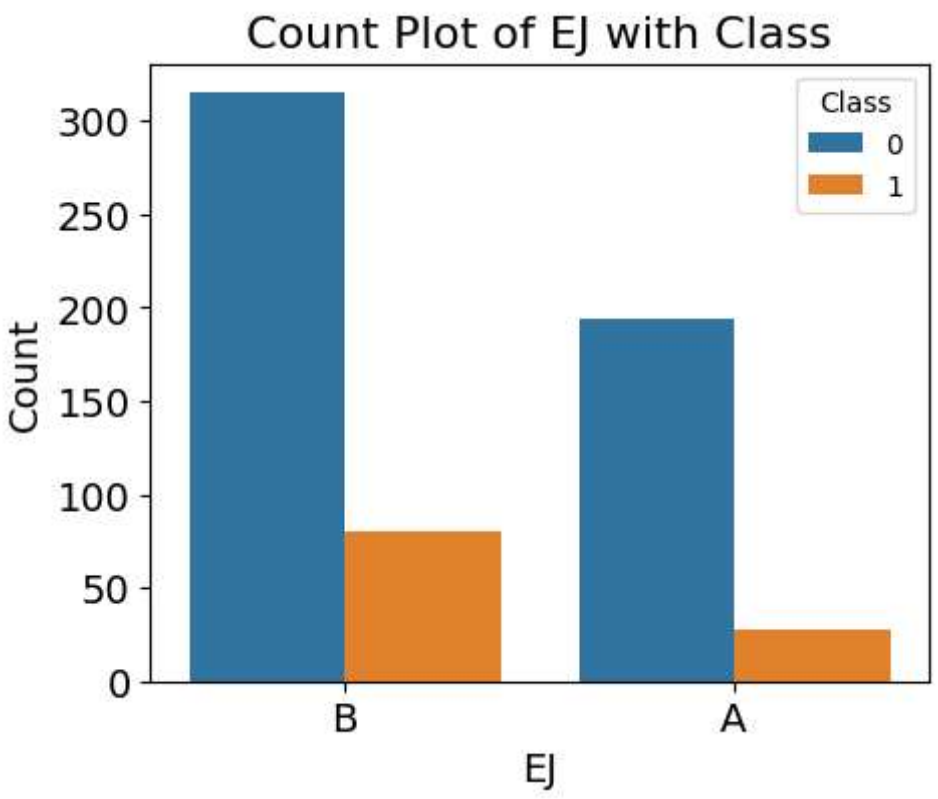
# Create the count plot
sns.countplot(data=df_train, x='EJ', hue='Class')

# Set the labels and title
plt.xlabel('EJ', fontsize=14)
plt.ylabel('Count', fontsize=14)
plt.title('Count Plot of EJ with Class', fontsize=16)

# Adjust the tick label size
plt.tick_params(axis='x', which='major', labelsize=14)
plt.tick_params(axis='y', which='major', labelsize=14)

# Add a legend
plt.legend(title='Class')

plt.show()
```



3. Data Pre-processing for Model Data

3.1. Missing Value Imputation - kNN Imputer

Missing value imputation using kNN (k-nearest neighbors) imputer is a technique that fills in missing values in a dataset by estimating them based on the values of their k nearest neighbors. It leverages the similarities between samples to impute missing values, making it a useful method for handling incomplete data.

In [11]:
```
# Initialize the KNNImputer with the desired number of neighbors
imputer = KNNImputer(n_neighbors=5)

# Perform KNN imputation
df_train_imputed = pd.DataFrame(imputer.fit_transform(df_train[df_train_numerical.columns]), columns=df_train_numerical
df_test_imputed =pd.DataFrame(imputer.transform(df_test[df_train_numerical.columns]), columns=df_train_numerical.column
```

In [12]:
```
# Check if there are still missing values in the train and test data sets
df_train_null = df_train_imputed[df_train_imputed.isnull().any(axis=1)]
df_test_null = df_test_imputed[df_test_imputed.isnull().any(axis=1)]

# Display the rows with null values
print('No. of records with missing value in Train data set after Imputation : {}'.format(df_train_null.shape[0]))
print('No. of records with missing value in Test data set after Imputation : {}'.format(df_test_null.shape[0]))

# Check the shape of the train and test data set
```

```
print('=' * 50)
print('Shape of the Train data set : {}'.format(df_train_imputed.shape))
print('Shape of the Test data set : {}'.format(df_test_imputed.shape))
```

```
No. of records with missing value in Train data set after Imputation : 0
No. of records with missing value in Test data set after Imputation : 0
==================================================
Shape of the Train data set : (617, 55)
Shape of the Test data set : (5, 55)
```

In [13]:
```
# Replace the imputed columns in the train data sets
df_train_2 = df_train.drop(df_train_numerical.columns, axis=1)
df_train_2 = pd.concat ([df_train_2, df_train_imputed], axis=1)

# Replace the imputed columns in the test data sets
df_test_2 = df_test.drop(df_train_numerical.columns, axis=1)
df_test_2 = pd.concat ([df_test_2, df_test_imputed], axis=1)

# Check the shape of the train and test data set
print('Shape of the Train data set : {}'.format(df_train_2.shape))
print('Shape of the Test data set : {}'.format(df_test_2.shape))
```

```
Shape of the Train data set : (617, 58)
Shape of the Test data set : (5, 57)
```

3.2. Data Standarization for Numercial Features

The RobustScaler is a data preprocessing technique available in the scikit-learn library in Python. It is used to scale numerical data in a robust manner, meaning it is less sensitive to the presence of outliers compared to other scaling methods like standardization or min-max scaling.

In [14]:
```
# Create a RobustScaler object
scaler = RobustScaler()

# Extract the index
index = df_train_2.index

# Fit the scaler to the data and transform it
scaler_train = scaler.fit_transform(df_train_2[df_train_numerical.columns])
scaler_df_train = pd.DataFrame(scaler_train, columns=df_train_numerical.columns)

# Reassign the index to the scaled DataFrame
scaler_df_train.index = index
print('Shape of Scaled Train Data Set: {}'.format(scaler_df_train.shape))

# Extract the index
index = df_test_2.index

scaler_test = scaler.transform(df_test_2[df_train_numerical.columns])
scaler_df_test = pd.DataFrame(scaler_test, columns=df_train_numerical.columns)

# Reassign the index to the scaled DataFrame
scaler_df_test.index = index
print('Shape of Scaled Test Data Set: {}'.format(scaler_df_test.shape))
```

```
Shape of Scaled Train Data Set: (617, 55)
Shape of Scaled Test Data Set: (5, 55)
```

In [15]:
```
# Replace the scaled columns in the train data sets
df_train_2 = df_train_2.drop(df_train_numerical.columns, axis=1)
df_train_2 = pd.concat ([df_train_2, scaler_df_train], axis=1)

# Replace the imputed columns in the test data sets
df_test_2 = df_test_2.drop(df_train_numerical.columns, axis=1)
df_test_2 = pd.concat ([df_test_2, scaler_df_test], axis=1)

# Check the shape of the train and test data set
print('Shape of the Train data set : {}'.format(df_train_2.shape))
print('Shape of the Test data set : {}'.format(df_test_2.shape))
```

```
Shape of the Train data set : (617, 58)
Shape of the Test data set : (5, 57)
```

3.3. Data Encoding for Categorical Features

CATBoostEncode, or CatBoostEncoder, is a categorical encoding technique specifically designed for the CatBoost algorithm. CatBoost is a gradient boosting algorithm that is known for its strong performance in handling categorical features. The CatBoostEncoder is a specialized encoding method that is compatible with the CatBoost algorithm and aims to effectively encode categorical variables for improved model performance.

In [16]:
```
# Load the CatBoost Encoder
CATBoostENCODE = encoders.CatBoostEncoder()

categorical_cols = ['EJ']

# Use CatBoost to encode the categorical values
encoder_train = CATBoostENCODE.fit_transform(df_train[categorical_cols], df_train['Class'])
encoded_df_train = pd.DataFrame(encoder_train)
print('Shape of the Encoded Train Data Set: {}'.format(encoded_df_train.shape))

encoder_test = CATBoostENCODE.transform(df_test[categorical_cols])
```

```
encoded_df_test = pd.DataFrame(encoder_test)
print('Shape of the Encoded Test Data Set: {}'.format(encoded_df_test.shape))
```

```
Shape of the Encoded Train Data Set: (617, 1)
Shape of the Encoded Test Data Set: (5, 1)
```

In [17]:
```
# Replace the encoded columns in the train data sets
df_train_2 = df_train_2.drop(categorical_cols, axis=1)
df_train_2 = pd.concat ([df_train_2, encoded_df_train], axis=1)

# Replace the imputed columns in the test data sets
df_test_2 = df_test_2.drop(categorical_cols, axis=1)
df_test_2 = pd.concat ([df_test_2, encoded_df_test], axis=1)

# Check the shape of the train and test data set
print('Shape of the Train data set : {}'.format(df_train_2.shape))
print('Shape of the Test data set : {}'.format(df_test_2.shape))
```

```
Shape of the Train data set : (617, 58)
Shape of the Test data set : (5, 57)
```

3.4. SelectKBest Method from SKLearn for Feature Selection

SelectKBest is a feature selection method in Scikit-learn (sklearn) library, which selects the top k features (columns) from a dataset based on some statistical test score.The basic idea behind SelectKBest is to evaluate the statistical significance of each feature using a scoring function and select the top k features with the highest scores.

In [18]:
```
# Before we do the oversampling, we will split the data into training and testing data for model training
train = df_train_2.drop(['Id', 'Class'], axis=1)
test = df_train_2['Class']

# Renaming the columns
test.columns = ['Class']
```

In [19]:
```
threshold = 0.1
t_score = 5

# Initiate the SelectKBest function
# For regression tasks: f_regression, mutual_info_regression
# For classification tasks: chi2, f_classif, mutual_info_classif
fs = SelectKBest(score_func=f_classif, k=len(train.columns))

# apply feature selection
X_selected = fs.fit_transform(train, test.values)
print('Befoe the SelectKBest = {}'.format(train.shape))

new_features = [] # The list of features less than the p-values
drop_features = [] # The list of features higher than the p-values

for i in range(len(train.columns)):
    print('Feature {}: {:.3f} with p-value {:.3f}'.format(train.columns[i], fs.scores_[i], fs.pvalues_[i]))
    if fs.pvalues_[i] <= threshold and fs.scores_[i] >= t_score:
        new_features.append(train.columns[i])
    else:
        drop_features.append(train.columns[i])

X_selected_final =  pd.DataFrame(X_selected)
X_selected_final.columns = train.columns
#    print(X_selected_final.shape)
X_selected_final = X_selected_final[new_features]
#    print(X_selected_final.shape)

print('=' * 30)
print('After the SelectKBest = {}'.format(X_selected_final.shape))
print('Drop-out Features = {}'.format(len(drop_features)))
```

# Drop out low informative features for model training
train = train.drop(drop_features, axis=1)
df_train_2  = df_train_2.drop(drop_features, axis=1)
df_test_2  = df_test_2.drop(drop_features, axis=1)
```

3.5. Oversampling with SMOTE (Synthetic Minority Over-sampling Technique)

SMOTE (Synthetic Minority Over-sampling Technique) is a technique to address the problem of imbalanced datasets. Imbalanced datasets occur when the classes in the target variable are not represented equally, resulting in a skewed distribution. This is a common issue in many real-world classification problems, such as fraud detection, rare disease prediction, or anomaly detection.

In [21]:
```python
X_train, X_test, y_train, y_test = train_test_split(train, test, test_size=0.3)

print('Shape of train : {}'.format(X_train.shape))
print('Shape of test : {}'.format(X_test.shape))
print('='*50)
print('Shape of df_train (incl. ID and Class): {}'.format(df_train_2.shape))
print('Shape of df_test (incl. ID): {}'.format(df_test_2.shape))
```

```
Shape of train : (431, 28)
Shape of test : (186, 28)
==================================================
Shape of df_train (incl. ID and Class): (617, 30)
Shape of df_test (incl. ID): (5, 29)
```

In [22]:
```python
# Load the SMOTE library
smote = SMOTE(sampling_strategy={0: 360, 1: 360})
# df_train_numerical = df_train.drop(['Id', 'EJ', 'Class'], axis=1)

X_smote, y_smote = smote.fit_resample(X_train, y_train)
print("length of original data is ",len(df_train_2))
print("Proportion of True data in original data is {:.2%}".format(len(y_train[y_train==1])/len(y_train)))
```

```
print("Proportion of False data in original data is {:.2%}".format(len(y_train[y_train==0])/len(y_train)))
print("length of oversampled data is ",len(X_smote))
print("Proportion of True data in oversampled data is {:.2%}".format(len(y_smote[y_smote ==1])/len(y_smote)))
print("Proportion of False data in oversampled data is {:.2%}".format(len(y_smote[y_smote ==0])/len(y_smote)))
```

```
length of original data is  617
Proportion of True data in original data is 16.94%
Proportion of False data in original data is 83.06%
length of oversampled data is  720
Proportion of True data in oversampled data is 50.00%
Proportion of False data in oversampled data is 50.00%
```

4. Modelling

In [23]:
```
# Parameter Setup
p_folds = 3
p_iter = 1000
p_estimators = 1000
p_learning_rate = 0.01
```
